INTRODUCTION

IMRT and VMAT are irradiation methods that can administer a higher dose to the target and reduce the dose to normal tissue simultaneously due to the steep dose gradient. However, IMRT and VMAT present more complex irradiation methods compared to 3D-CRT [1]. Consequently, IMRT and VMAT are more likely to cause serious accidents than 3D-CRT. There has been serious radiation accidents reported in clinical radiotherapy [2]. To prevent such accidents patient-specific pre-treatment verification was deemed necessary. Furthermore, a report from the Netherlands in 2010 found that dose errors which could not be detected even after patient-specific pre-treatment verification were detected by in vivo dosimetry (IVD) using an electronic portal imaging device during treatment [3]. The importance of dose verification during treatment has been brought to attention [3]. The UK, "Towards Safer Radiotherapy", recommends that IVD monitoring protocols should be prepared for most patients at all sites, at the start of treatment [4]. This research is to investigate the possibility of detecting errors during treatment by performing basic experiments that create an error plan for the stop position of MLC using a gantry-mounted transmission detector.

AIM

The purpose of this research is to investigate the possibility of detecting errors during treatment using a gantry-mounted transmission detector

MATERIAL AND Method

Materia

A real-time monitoring system to detect errors of dose and MLC position during treatment system: the Delta⁴ Discover[®] (D4D) system (ScandiDos AB, Uppsala, Sweden).

This system consists of Delta⁴ Phantom + (D4P) (ScandiDos AB, Uppsala, Sweden) used for patient-specific pre-verification and D4D gantry-mounted transmission detector.

Medical Linear Accelerator: TrueBeam energy 10X (Varian medical systems, California, USA)

Treatment planning system: Eclipse versions 11.0 (Varian medical systems California, USA)

Method

We compared the result of dose verification using D4D of a gantry-mounted transmission detector and D4P

- Ten prostate treatment plans were evaluated
- · The simulation plan for detecting errors during treatment consists of the MLC of all control points was displaced from B side (X1 side) to A side (X2 side) by 0.5, 1.0, 1.5, 2.0, 2.5 and 3.0mm from the original plan
- · Dose deviation (DD), distance-to-agreement (DTA), and gamma index analysis (GA) were used to validate the dose distribution.
- The evaluation criteria were DD at 3%, DTA at 2mm, and GA at 3.0% / 2.0mm, and the threshold was evaluated at 10%.
- · We performed a significant difference test using Welch's t-test as an evaluation of the significant difference between the original plan (no MIC error) and the simulated plans.

RESULTS Evaluation of VMAT for ten prostate cancer patients

DD

The horizontal axis shows the D4P pass-ratio, and the vertical axis shows the D4D pass-ratio. The line connecting the values where D4P and D4D are equal is defined as the reference line.

CONCLUSIONS

be verified during treatment.

were measured

Pass-ratio · When the MLC position error exceeds 1.5 mm, the D4D DD pass-ratio gets higher than that of D4P, and this tendency increases as the MLC position error increases.

- When the MLC position error exceeds 0.5 mm, the value of D4D becomes higher than the value of D4P, and the tendency is similar to that of DD. · When the MLC position error exceeds 1.0 mm, the value of D4D becomes higher than the value of D4P, similar to DD and DTA
- Welch's t-test
- · For D4D When DD, DTA, and GA parameters were used, the detection of MLC error was 2.0 mm for DD and 1.5 mm for DTA and GA.
- For D4P. MLC error detection was 2.0 mm for DD. 1.0 mm for DTA. and 1.5 mm for GA.
- We compared the result of dose verification using D4D of a gantry mounted transmission detector and the D4P. D4D has almost the same detection power as D4P, and can be detected with an MLC position error of 1.5 mm or more by using DTA or GA. Based on our results, the transmission detector Delta⁴ Discover is suitable for In-vivo Dosimetry.
